

# Connectomics

**Large-scale synaptic-resolution brain mapping in academia-industry collaborations.**

Michał Januszewski  
Google Research

TEAMS ›

# Connectomics

Our goal is to leverage Google expertise and resources to advance understanding of the structure and function of the brain.

## Automated 3d Brain Reconstruction

We develop algorithms and software for automating the process of aligning, segmenting, and annotating petabyte-scale 3d images of brain tissue.

TEAMS ›

# Connectomics

Our goal is to leverage Google expertise and resources to advance understanding of the structure and function of the brain.

## Visualization and Infrastructure

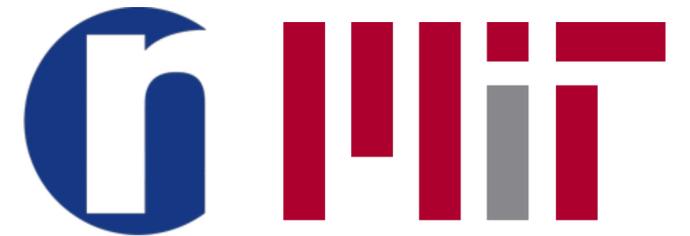

We develop software such as **TensorStore** and **Neuroglancer** which helps store, process, and visualize large n-dimensional images and volumes.

# Why a collaboration?

- Common goal.
- Large-scale, complex project.
- **Complementary expertise.**
- Sufficient shared understanding of the involved domains.

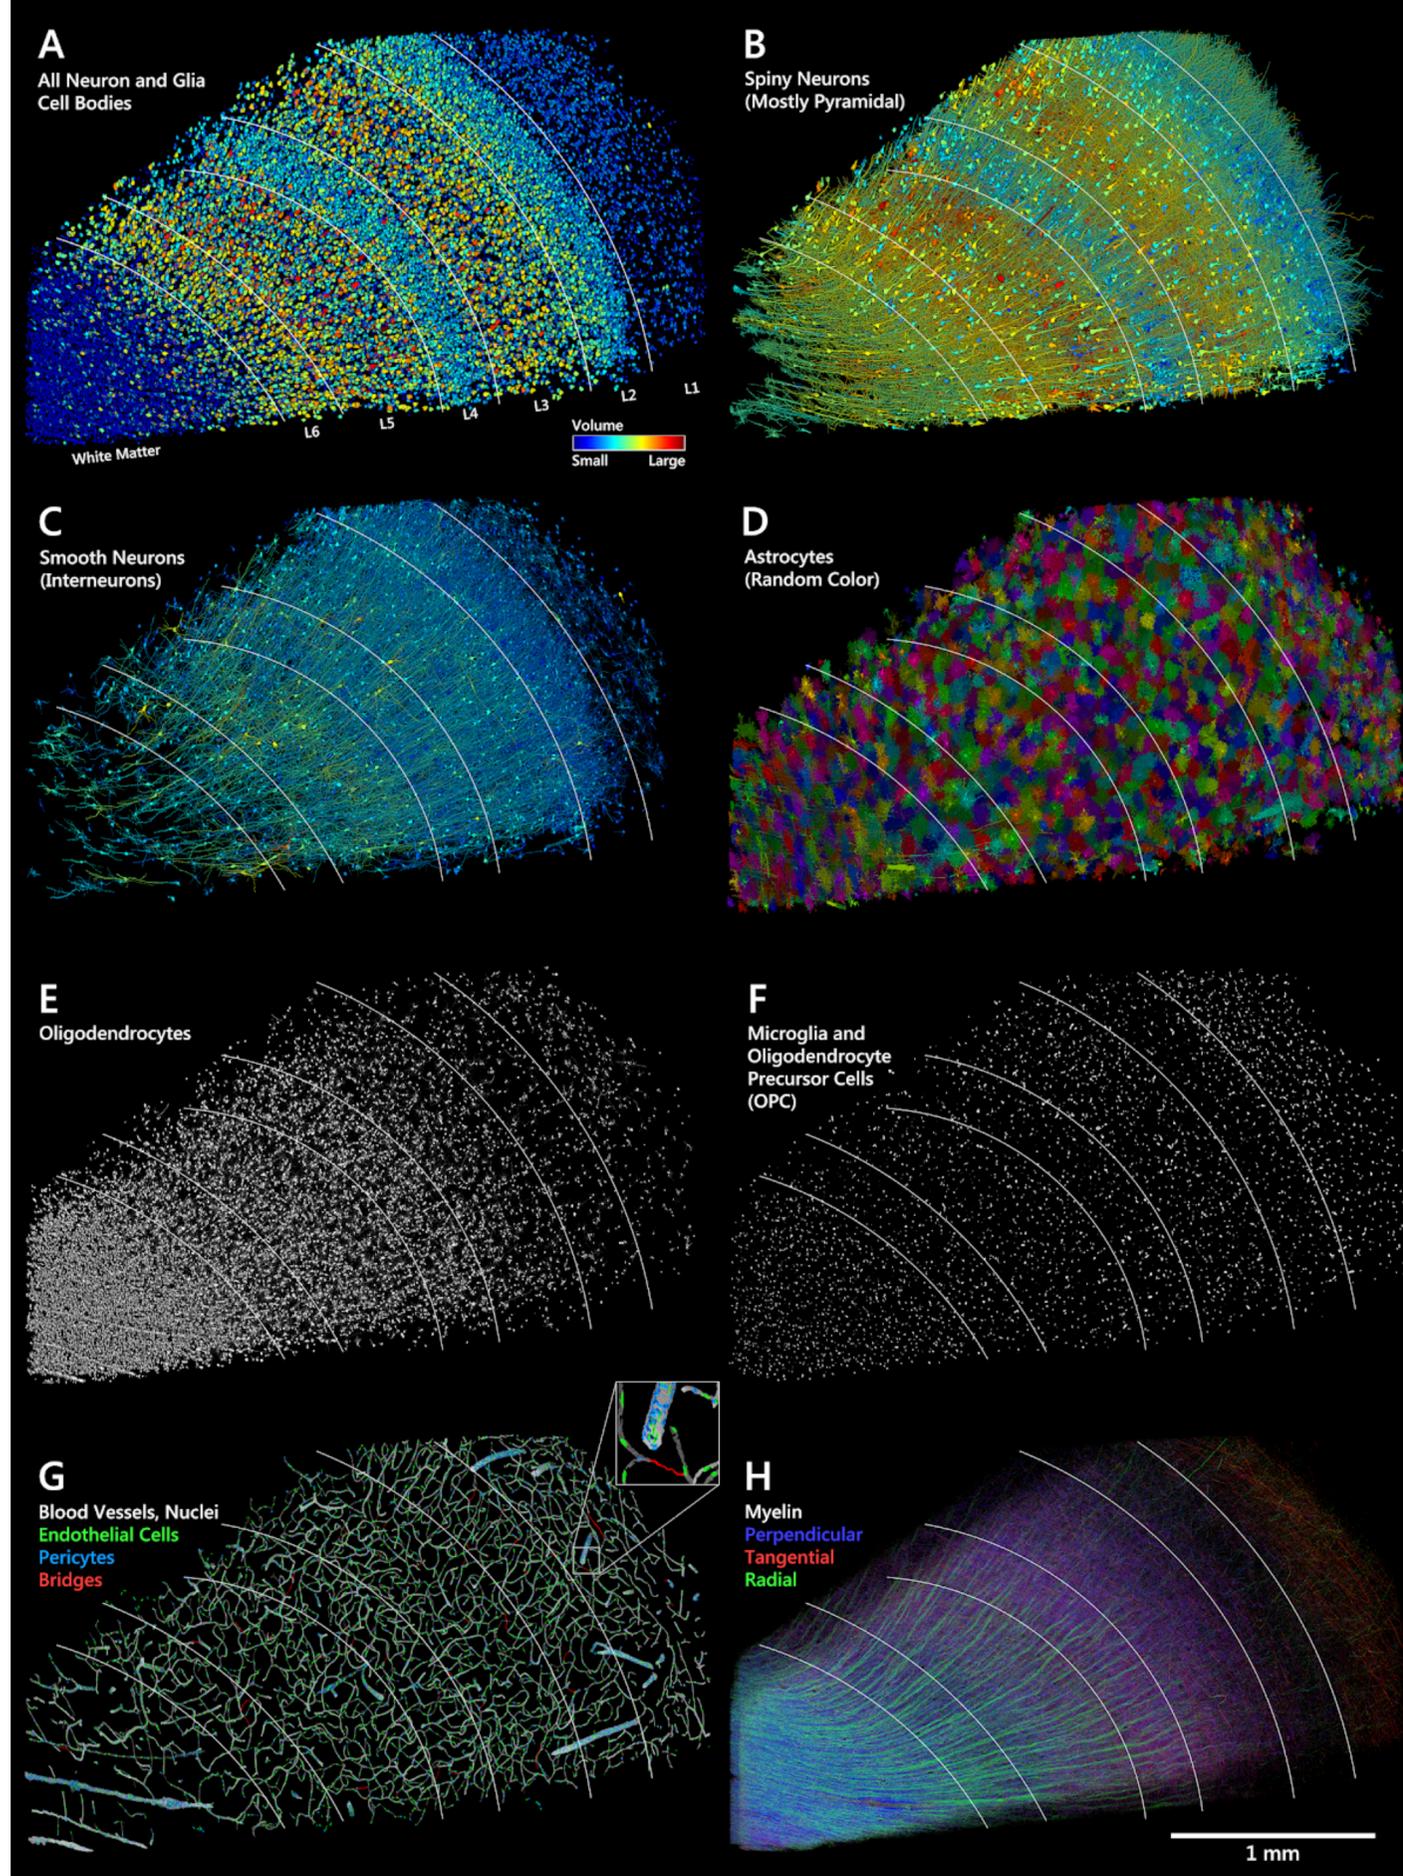

# h01: 1 mm<sup>3</sup> of human cortex

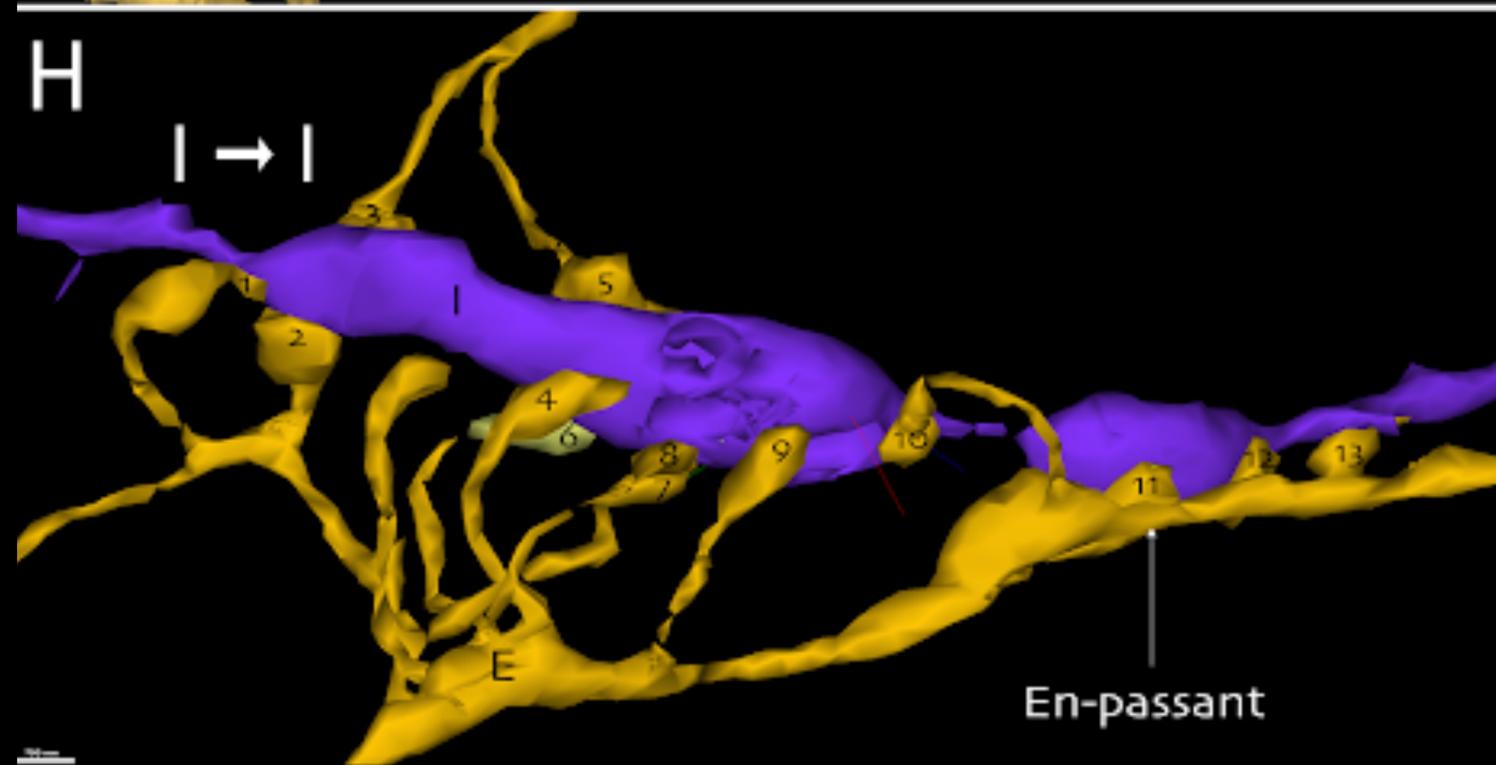

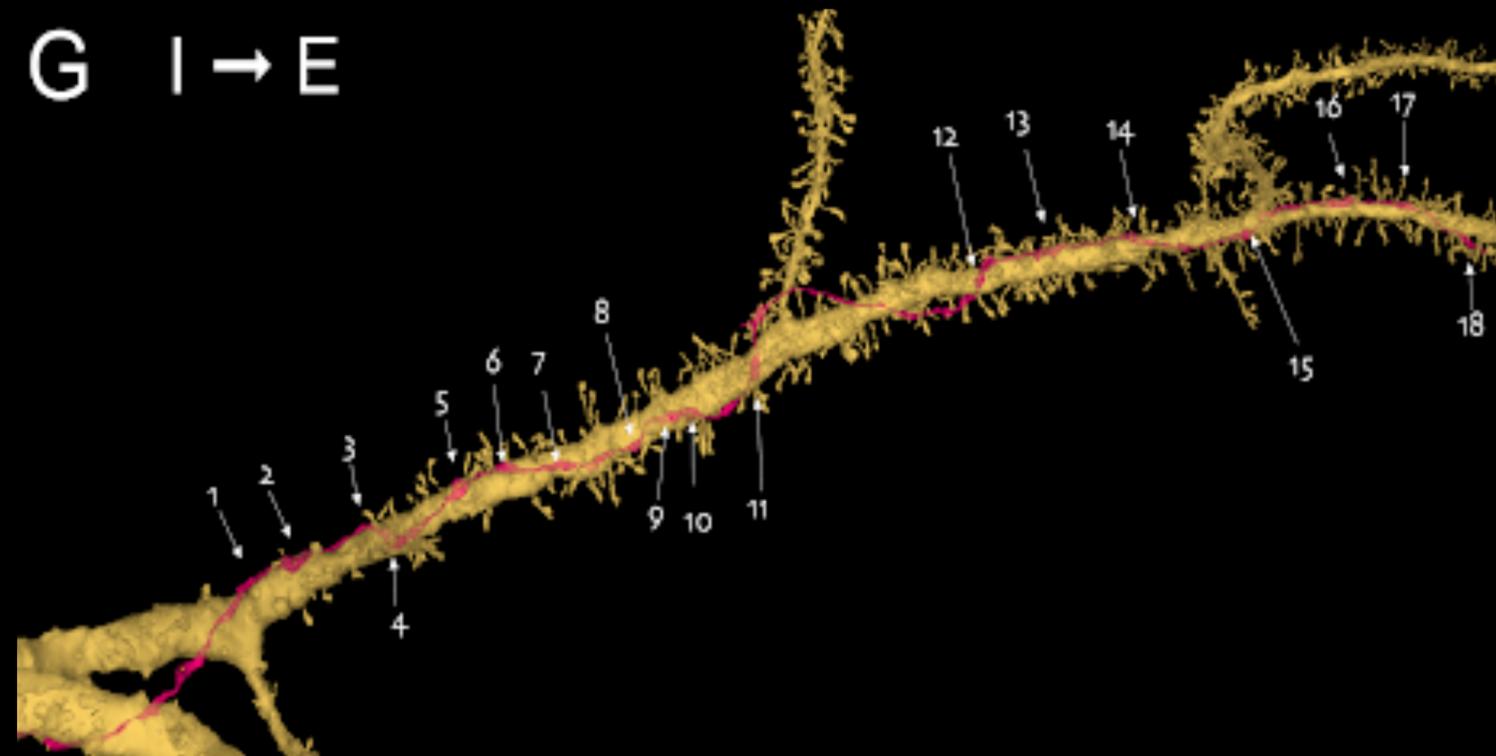

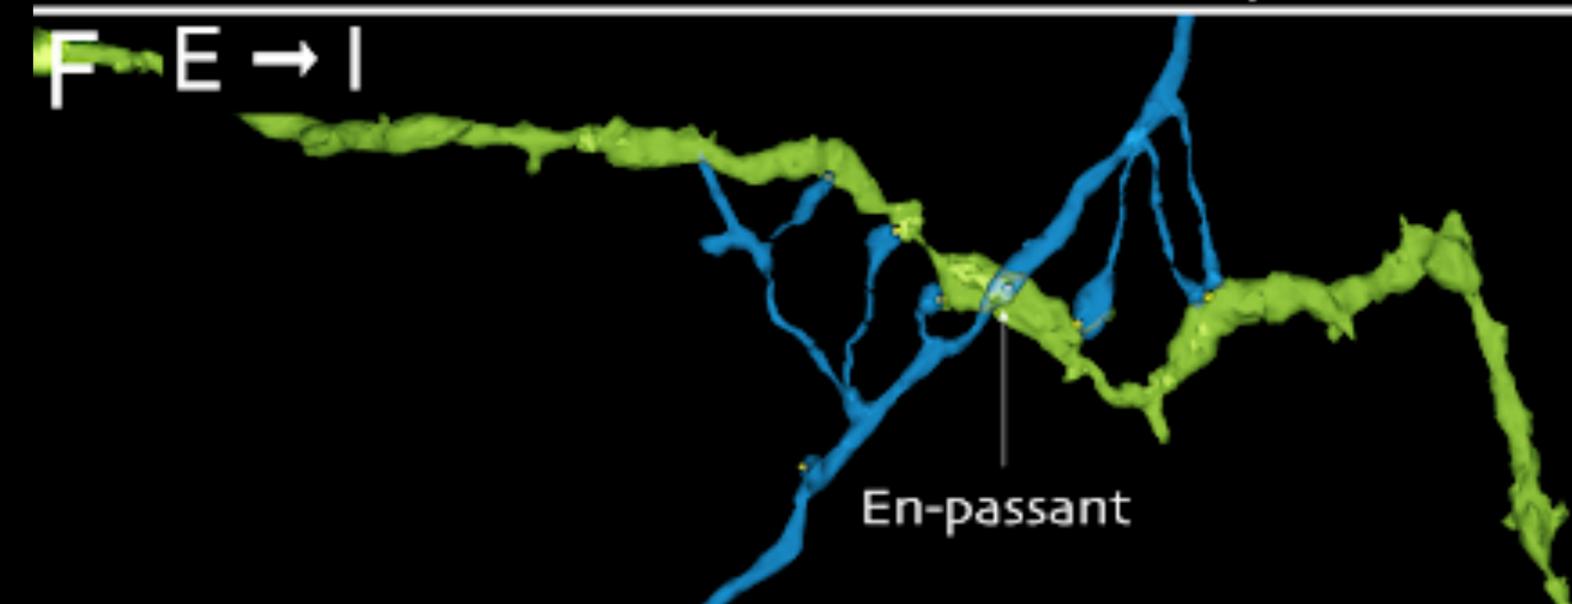

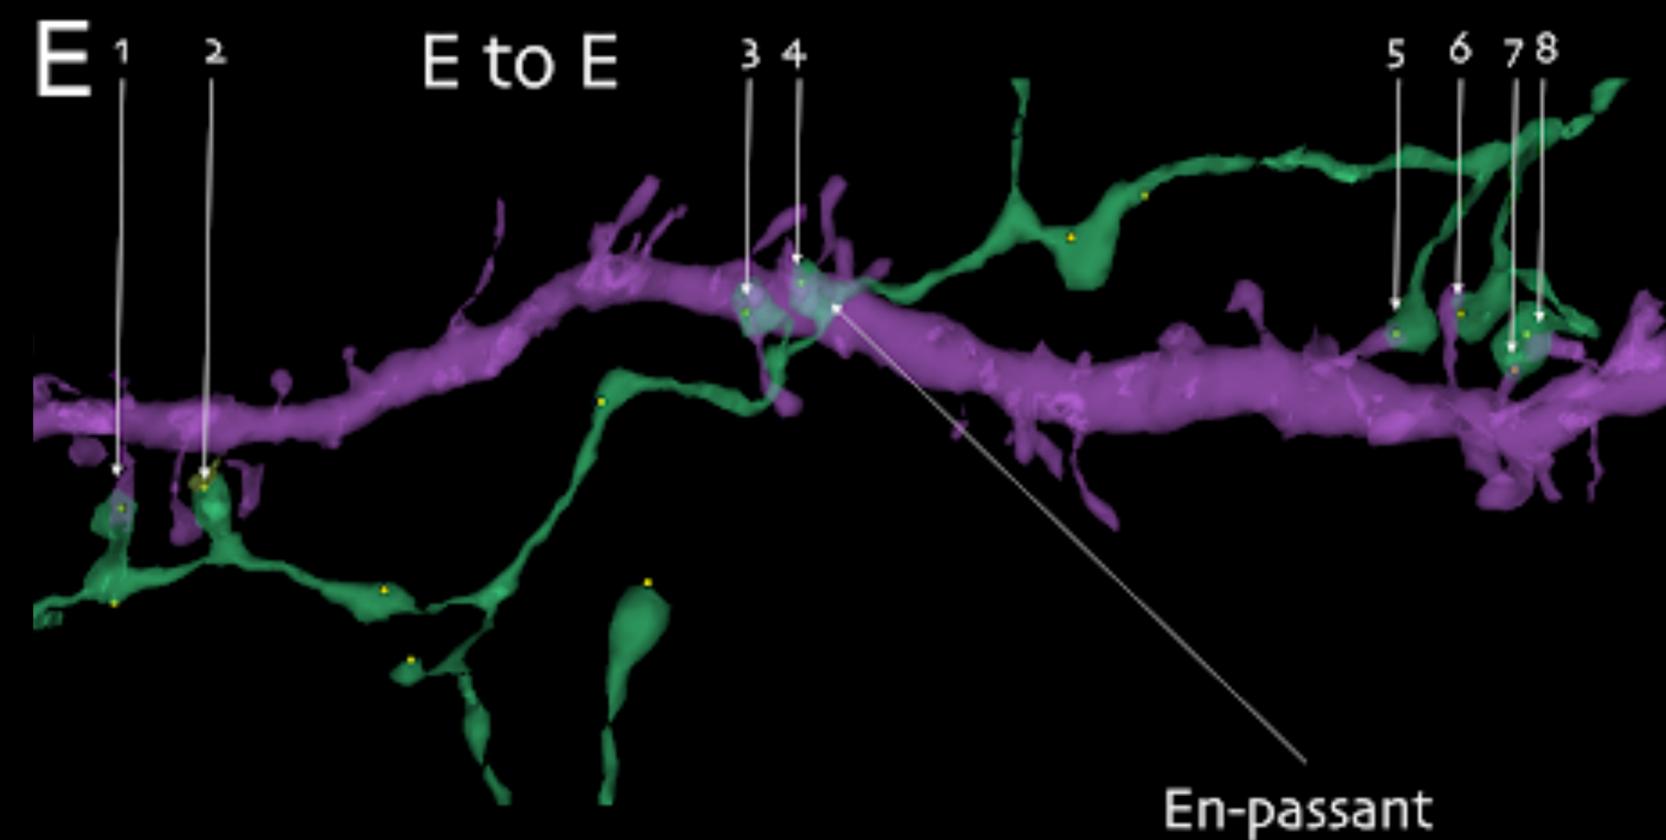

- Collaboration with Lichtman lab, Harvard University
- 5,000 sections
- 326 days of imaging time
- 1.4 PB of imagery
- 57,216 cells
- 133.7M synapses
- Available online: <https://h01-release.storage.googleapis.com/landing.html>

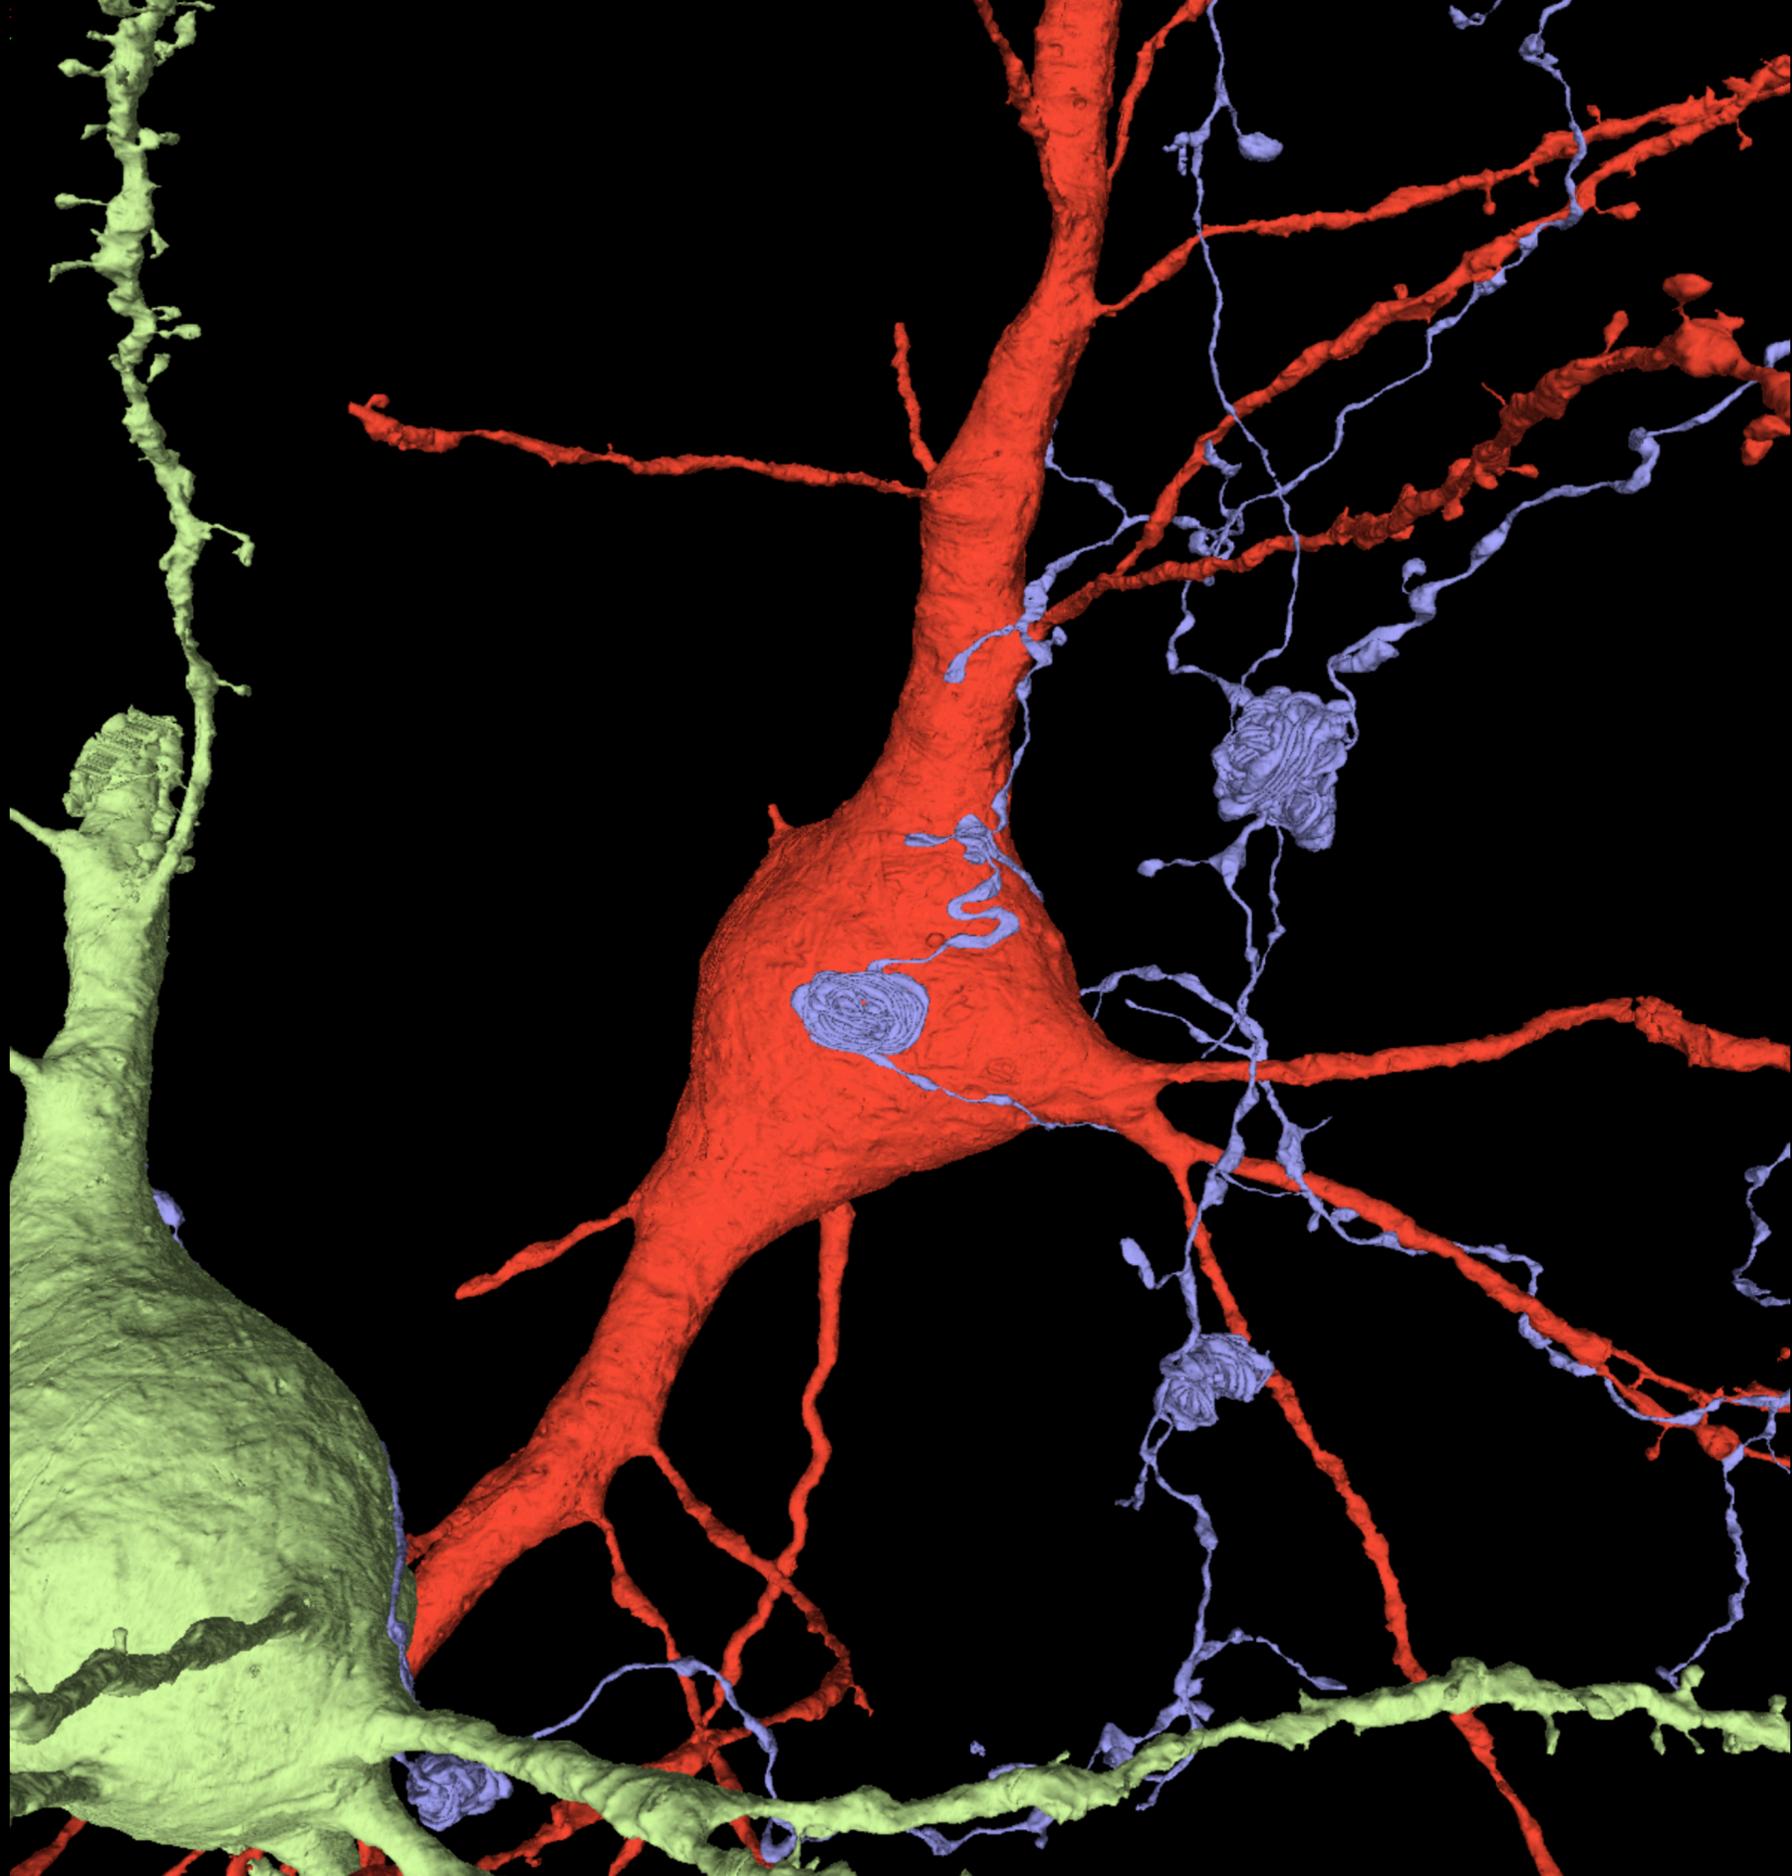

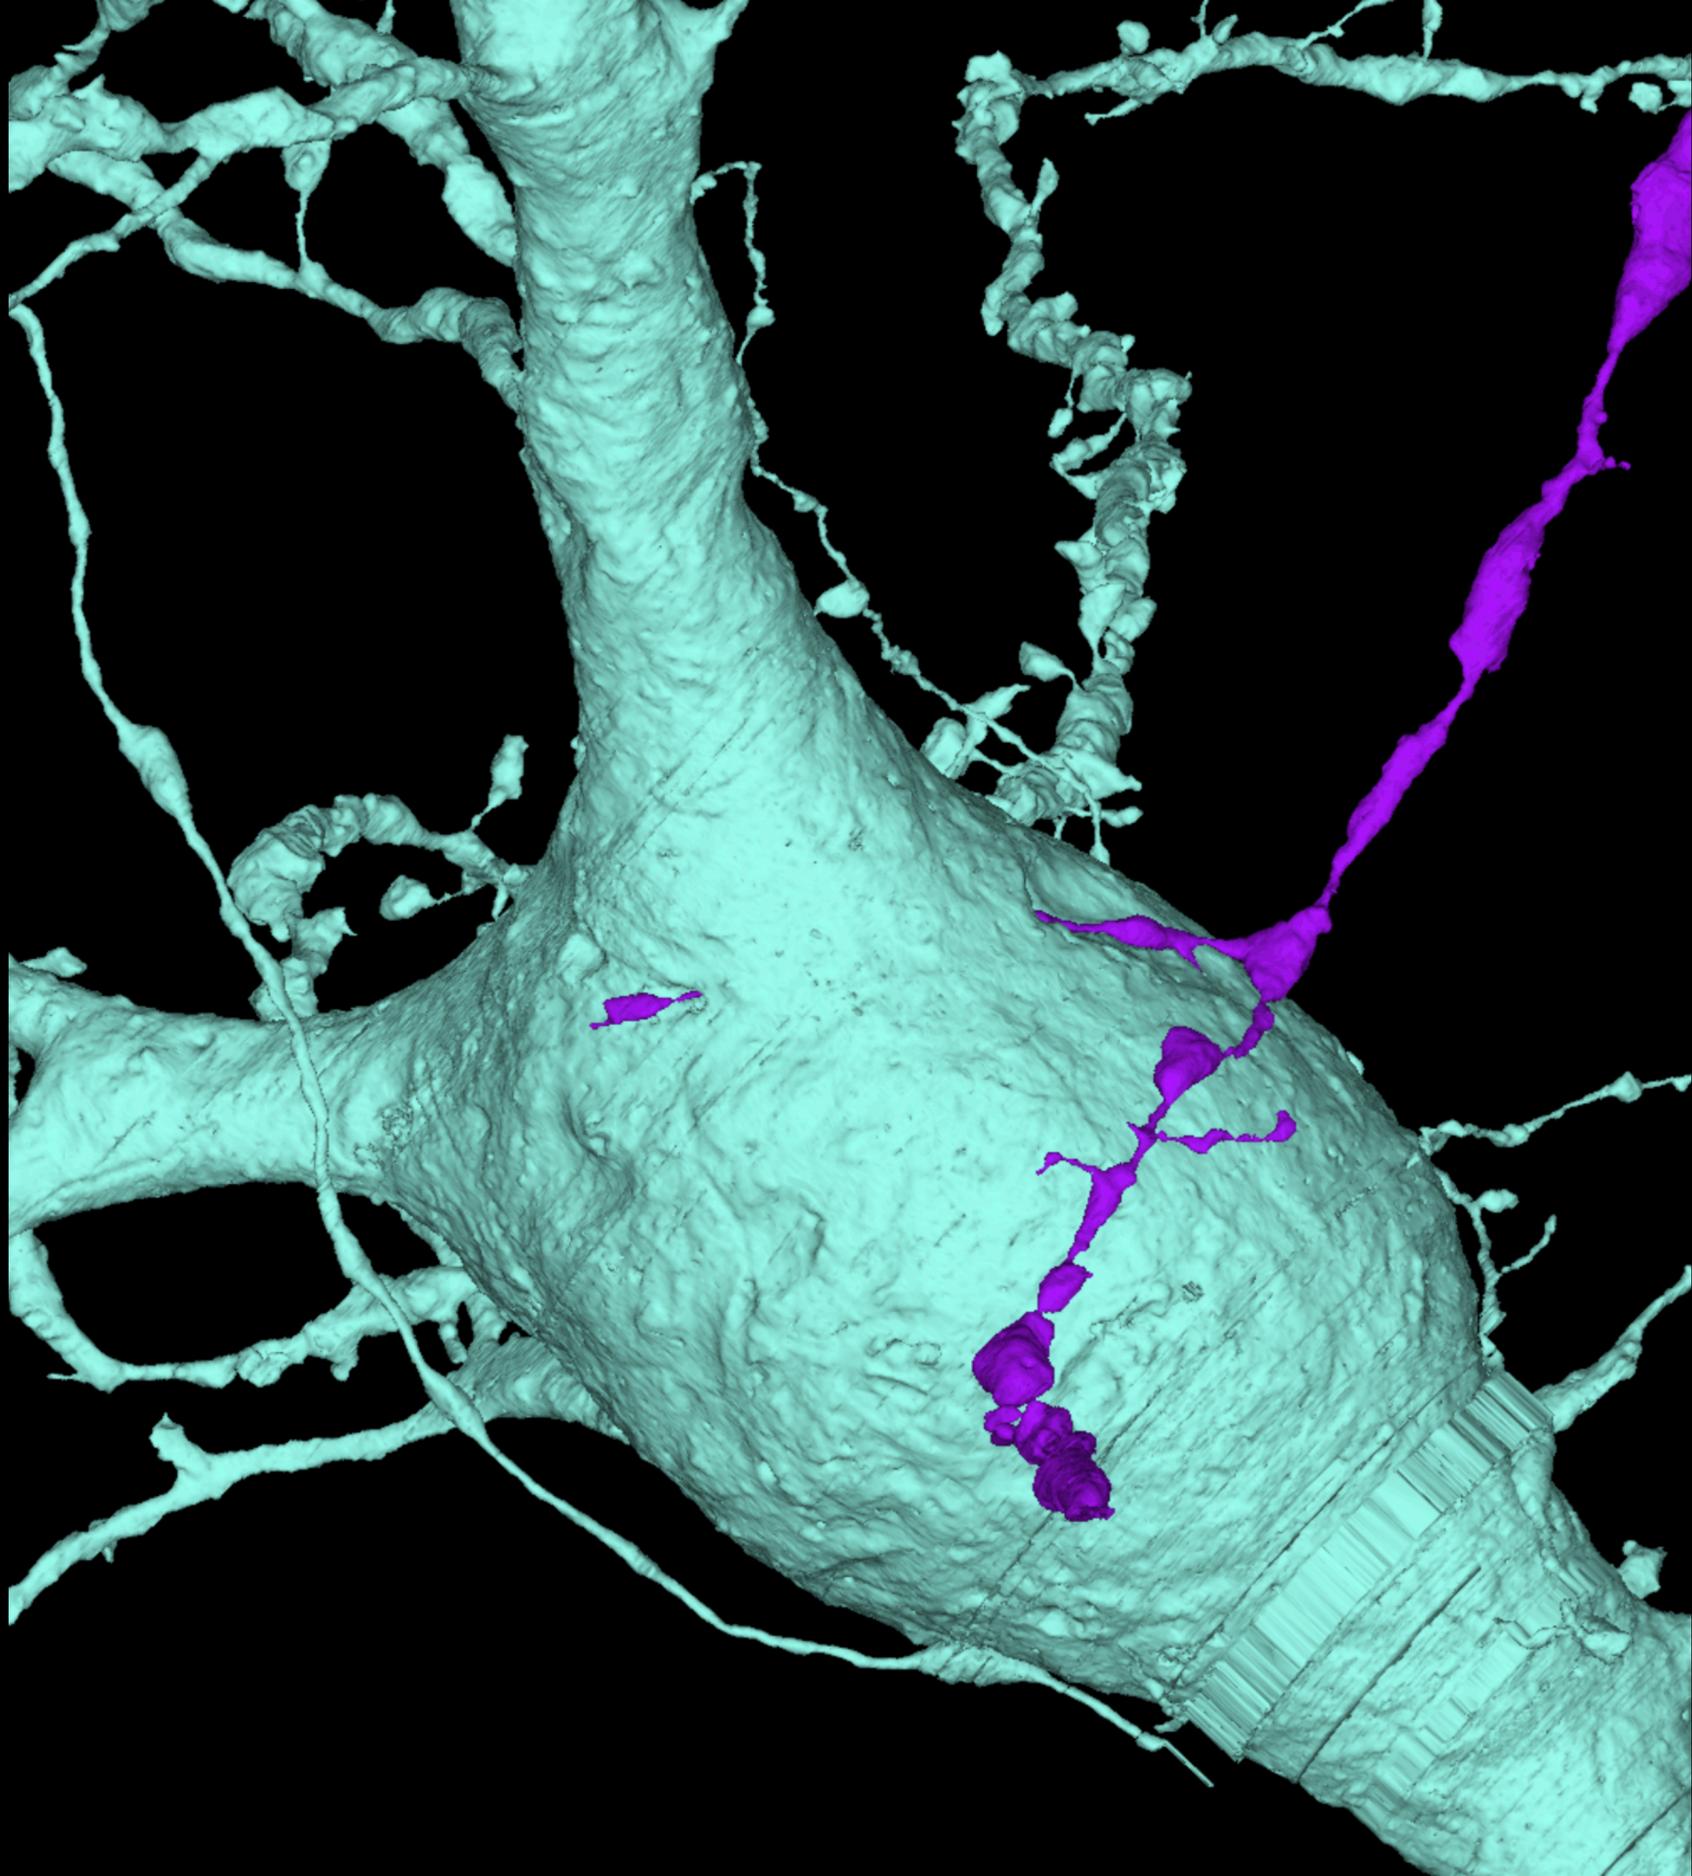

# Initial findings

- Complete cell census;  
~2:1 glia:neuron ratio.
- Presence of axons with unusual morphology ("whorls").
- Chandelier interneurons innervating each other's axon initial segments.
- Presence of rare multi-synaptic contacts.

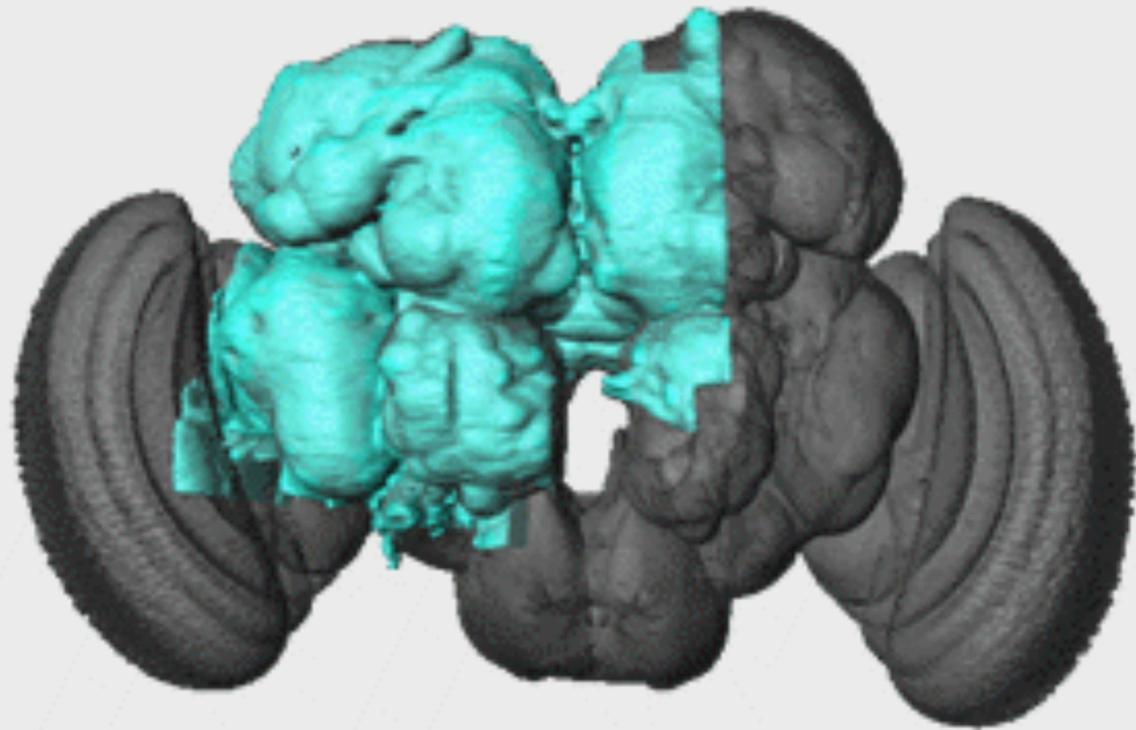

# Hemibrain

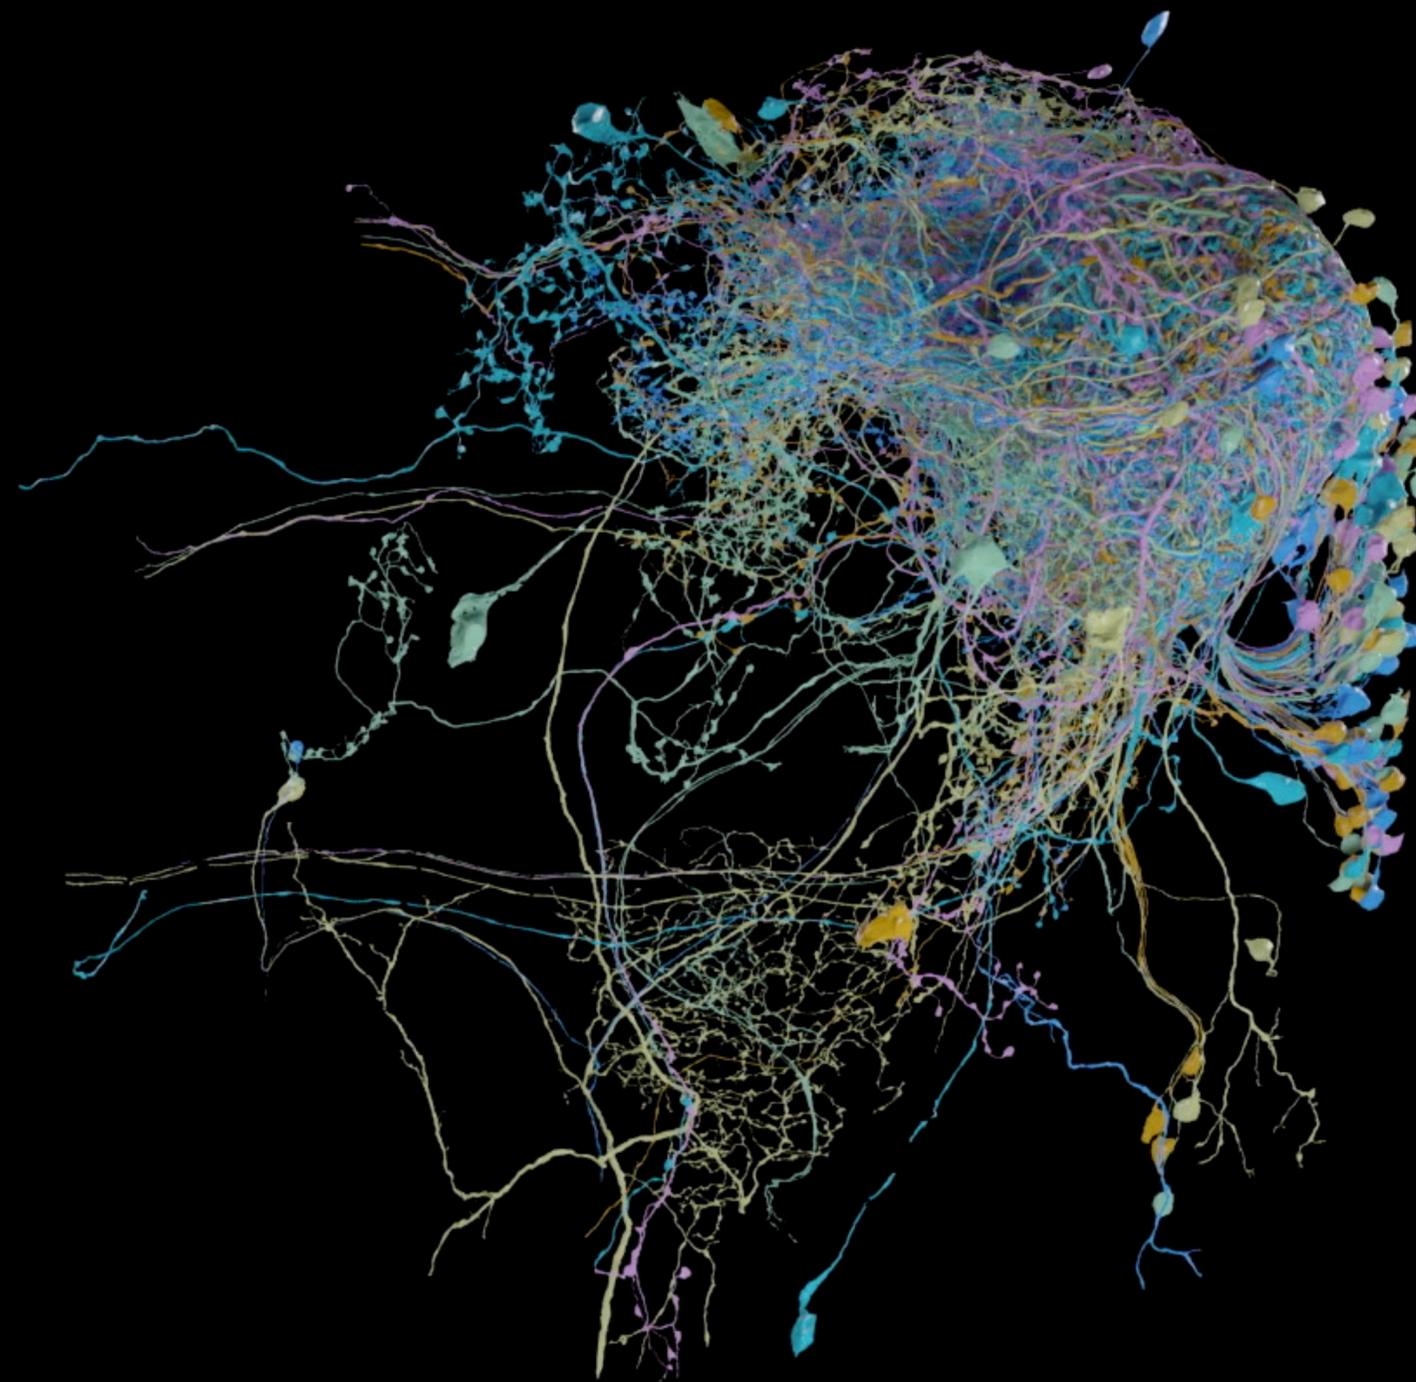

The hemibrain dataset encompasses the part of the fly brain highlighted here in blue. This region includes neurons involved in learning, navigation, smell, vision, and many other functions.

- Central part of the *Drosophila* brain
- 25,000 neurons
- 50 person-years of proofreading
- Public resource:  
<https://www.janelia.org/project-team/flyem/hemibrain>

Details in:

Scheffer, Louis K., et al. "A connectome and analysis of the adult *Drosophila* central brain." *Elife* 9 (2020): e57443.

*It should be kept in mind that although most of the currently operating systems make extensive use of the computer for bookkeeping, 3-D display, and data analysis, they still require the slow manual input of graphical information. However, it seems quite clear that the rapid advances in electronics will make **more and more automation possible** at a reasonable cost. **Within a few years we can expect that systems will be available that can easily recognize and digitize some features automatically, leaving for the investigator only those cases that are difficult or ambiguous.** The greater speed with which the analysis can then be done should make possible a great increase in the use of such systems for both basic research and practical problems, such as those of the clinical pathologist. Thus two quite separate issues will be involved in future developments of this technique: (a) the technical problems associated with increasing automation and reducing equipment cost; and (b) the expanded exploration of ways in which these techniques can be applied to new and different scientific as well as clinical problems*

# Summary

- Connectomics demands **extreme accuracy and scale**. Customized ML approaches make this possible.
- Successful projects bring together lots of complementary expertise to a single collaboration.
